PRIMARY AND SECONDARY TEACHERS SALARIES IN ONTARIO:
A PUBLIC/PRIVATE SECTOR COMPARISON

In a perfectly competitive labour market, the equilibrium wage rate, for any occupational group, will be determined by the forces of demand and supply, reflecting relative scarcity and the embodied value of labour for that group in the production of goods and/or services. While fluctuations in demand and supply will cause real wages to rise or fall, sometimes rapidly, the long term trend in wages, in competitive markets, will be determined by changes in the intrinsic characteristics of labour in a given occupation, representing equilibrium differentials.

There are, however, few perfectly competitive labour markets in the world. In Ontario, competitive markets have, in many instances, been replaced by a market structure more characteristically described as bilateral monopoly; an employer negotiating with a union or an employer's group negotiating with a union. There are, of course, exceptions. Casual workers, unskilled labour and independent professionals such as business executives tend to be part of competitive labour markets. Even in professional areas (doctors, lawyers, dentists, for example), there is a tendency for self-regulation of fees or regulation by a government agency.

In spite of the many non-competitive elements in labour

markets, the question remains as to whether or not there are any long term trends, both in absolute real incomes/salaries and relative salaries that suggest the existence of some underlying competitive forces or forces similar to competition? The question as to whether or not public sector wage determination is influenced by the same set of factors as in the private sector is dealt with in Auld and Wilton (1981) and Auld, et. al. (1981).

The purpose of this paper is to examine trends in the salaries/wages of Ontario elementary and secondary teachers and of education 'workers' more broadly defined (including college teachers and university professors).

Any analysis of wage rates, salaries or total compensation packages or rates of change in the foregoing that attempts to draw comparisons among or between employment groups must consider the following:

- i) the time period included in the analysis
- ii) the nature of the comparative reference groups
- iii) changes, over time, in the characteristics of the employment groups
- iv) the stability of labour market conditions, in general and for specific groups
- v) the sector (public or private) to which the groups are allocated

Discussion in this report revolves around the level and growth in the salaries of Ontario's primary and secondary school teachers salaries. This discussion concentrates on

the changes that have occurred in the absolute level of teachers' salaries over the past few years and makes some comparisons of these salaries with salary/income levels in other parts of the public sector and in selected professional groups in the private sector. As well, some suggestions on the forces that may have been working to alter the relative private and public sector incomes and wages will be offered.

The report is divided into six sections. Following this introduction, part II examines the trend in Ontario teachers and professors salaries for various years, 1966-1985, using Taxation Statistics and comparing these changes to the salaries of other public sector workers and several professional groups. Part III reviews trends in base wage rate increases for education workers in Ontario as reflected in collective agreements and compares this data with several other public sector groups and the private sector (in total).

Part IV compares elementary and secondary teachers salaries in Ontario with similar salaries in all of Canada and other education workers in Ontario; university professors and college teaching masters. Part V provides a summary of the data and in Part VI we conclude with some thoughts on the forces shaping these trends.

PART II: EVIDENCE FROM TAXATION STATISTICS

Revenue Canada collects detailed information on the sources of income from over one dozen employment groups including what have been categorized, in this paper, as public sector employees and private sector professionals. One of the groups is teachers and professors. This includes elementary and secondary school teachers as well as College and University faculty from both the public and private sectors with the former dominating the data. While the data are not published on a provincial basis, the Ontario data set was made available through a special printout. A comparison of relative incomes for Canada, as a whole, is found in Auld and Kitchen (forthcoming, 1988).

Table II-1 lists the average annual salary (or income from professional activity) for nine employment groups for selected years from 1966 to 1985 (1985 is the last year for which data are available). Earlier data are available in Auld and Grant (1977). While the absolute level of salaries differs for the various groups in each of the years, average annual earnings for teachers/professors increased by a factor of 6.1 over this period. Comparable factor increases for the other categories ranged from 5.6 for Federal employees to 1.8 for engineers and architects.

Table II-2 converts the data from Table II-1 into constant dollars (using the Consumer Price Index for Canada in 1981 dollars). In real terms, teachers/professors average

annual earnings grew by a factor of 1.7 while at the other end of the scale, similar earnings for lawyers and engineers and architects declined over this period.

Table II-3 provides data on the annual percentage change in reported earnings along with the overall annual average for the 20 year period. From this table, it is apparent that the teacher/professor group, as a whole, obtained larger increases than any of the other professional groups in the comparative data set. In fact, the average annual increase over the twenty years approached 10 percent. Federal public sector employees have performed almost as well, with dentists, municipal employees and doctors slightly behind.

Table II-4 is perhaps the simplest way of comparing relative salaries. Each element in the matrix represents the ratio of the average elementary or secondary teacher/professor salary, for that year, to the average salary of each of the nine groups. These results are illustrated more clearly in Figures II-1 and II-2. They reveal the significant gains made by the teacher/professor group, as a whole, relative to municipal and provincial employees (Figure II-1) and to engineers/architects and lawyers.

Finally, Figures II-3 and II-4 illustrate the cumulative increase in both real and nominal annual salaries over the 20 year period. These numbers simply reinforce, in a different way, the data in Table II-3.

PART III - DATA FROM COLLECTIVE BARGAINING AGREEMENTS IN ONTARIO

The Ontario Department of Labour collects and publishes detailed characteristics of all collective agreements involving 200 or more employees and has done so since the late 1960s. Unfortunately, elementary and secondary school teachers are not classified as a separate group but are included under the heading, Education, again encompassing all education workers whose employment contract is determined by collective bargaining. Elementary and secondary teachers are nonetheless, a significant part of this group. The basis for comparison, here, is the annual percentage base wage increase for education versus base wage increases for three other provincial public sector groups and the private sector, in total.

The data examined are extracted from one year collective bargaining agreements. While there is information on 2 and 3 year contracts, such contracts often include complex COLA (cost of living allowance) clauses making comparisons among groups very difficult. It should also be kept in mind that during the early 1980s, public sector wage controls suspended collective bargaining, producing gaps in the data (see Auld and Wilton, 1985).

Table III-1 displays the basic data, clearly highlighting the explosive nominal wage increases in the 1974-75 period and again in 1981-82. After adjusting for inflationary increases in each year, these dramatic nominal

gains are somewhat less spectacular. Over the twenty year period, the annual average wage increase for education was 8.27 per cent in nominal terms and 1.34 percent in real terms. This was the second lowest real increase for the five groups recorded in Table III-1. The largest average annual gain was in the health sector (10.27 percent in nominal terms and 3.34 percent in real terms). The smallest gain was in the local sector (8.15 percent nominal gain and 1.22 percent real gain). Before making quick comparisons and statements on the information in this Table, it must be remembered that base wage rate changes do not include gains received for merit, promotion or 'moving' through a grid scale of salary levels. The taxation data (PART II) revealed that over the same period (approximately), the average annual increase in nominal income was 9.88 per cent. The 1.61 difference can likely, therefore, be attributed to "progress through the ranks" and other characteristics of wage contracts.

The annual percentage increases of Table III-1 are converted into an index (with 1968=100) and shown in Table III-2 and Figures III-1 and III-2. The trends suggest that the education sector has not "out performed" other groups in salary increases. In fact, in relationship to the private sector, the index shows that from 1968 to 1987, the education sector fell 6.6 percentage points behind the private sector.

PART IV: STATISTICS CANADA DATA

While the data in PARTS II and III compared teaching salaries (University, Community College and elementary and secondary school teachers combined) with earnings for other selected professions, Table IV-1 records average annual salaries for each of the teaching components separately for the period from 1972/73 to 1987/88. For elementary teachers, the average annual salary at the beginning of this period was \$8,834 per year; for secondary teachers, it was \$11,602; for Community College teaching masters, the comparable figure was \$9,176; and for University faculty, the average salary was \$18,782. By 1987/88, the average elementary and secondary school teachers salary in Ontario had risen to \$41,528 and \$45,801 respectively. Comparable salaries for Community Colleges and Universities were \$46,626 and \$60,835 respectively (Table IV-1).

The increase in average salaries over this period was greatest for Teaching Masters in Community Colleges. More specifically, salaries, on average, increased by a factor of 5.1. By comparison, elementary school teachers salaries rose by a factor of 4.7 while secondary school teachers salaries increased by a factor of 3.9. University salaries grew by a factor of 3.2.

Table IV-2 converts the salary figures of Table IV-1 into constant dollars. After removing the inflationary component of salary increases (by deflating with the Consumer

Price Index for Canada), there is a considerably smaller increase for each category of teachers over the period.

Perhaps a more illustrative means of presenting information on comparative teaching salaries comes from a comparison of the change in the relative importance of the growth in elementary and secondary school teachers salaries vis-a-vis other teaching groups. Table IV-3 records these results while Figures IV-1 and IV-2 display them graphically. Figure IV-1 shows that elementary salaries have grown more quickly than University salaries from 1972/73 to 1987/88. Since 1975/76, the same trend is observed for Community College teaching masters. When the growth in elementary school salaries for Ontario and Canada are compared, there is no discernable change in the relative importance of Ontario elementary school teachers salaries.

Although the size of the absolute numbers differ, similar trends for secondary school teachers versus the other teaching groups are observed in Figure IV-2.

To gain some indication of the increase in salaries of the comparative groups from 1972/73 to the present, Table IV-4 records the annual percentage increase in earnings in both nominal and real terms. The average nominal and real increase over the fifteen year period was highest for Community College teaching masters and less, in descending order, for Canadian and Ontario elementary teachers, Canadian and Ontario secondary school teachers and University faculty

salaries (last row of Table IV-4). Figures IV-3 and IV-4 illustrate the results of the cumulative increase; that is, they represent the cumulative sum of the figures in Table IV-4 for the entire period. Both graphs generate similar trends; however, Figure IV-4 is probably more informative because it reflects the real increase in average earnings. In real terms, Community College salaries have displayed the greatest increase (58 percent). Next in line comes elementary salaries in Ontario (46 percent) and Canada; secondary salaries in both Ontario (26 percent) and Canada; and finally, University professors at 4 percent.

PART V: SUMMARY

Based on collective bargaining data available from the Ontario Government and taxation statistics from Revenue Canada, the education group performed quite well in terms of increases in average annual earnings. However, it must be emphasized that these two data sets do not provide disaggregated data on the various components of the teaching profession. Collective bargaining data in Ontario include base wage increases only for all education workers (University faculty, elementary and secondary teachers, Community College teaching masters and all support staff working in educational institutions) while taxation statistics aggregate elementary and secondary teachers with University professors and Community College teaching masters.

When the education sector is disaggregated by teaching group, some striking differences emerge. Over the past two decades, Community College instructors have surpassed, quite noticeably, elementary and secondary teachers and University faculty. As well, while University salaries have been higher than either of the other groups over this period, their rate of growth has been the slowest. In real terms, this increase amounted to about 4 percent over the period.

Finally, a comparison of Ontario's elementary and secondary teachers salaries with those for all of Canada reveal a high degree of consistency over the past 15 years with Ontario's average being slightly higher.

PART VI: CONCLUSION

The presentation, to this point, has not offered any conclusions as to why relative wages and/or salaries have changed over time or why differentials existed in the first place. A considerable amount of research has been done to explain differences and trends in wages, salaries and total compensation. The list of explanatory variables used in such studies includes:

- i) bargaining power of the union
- ii) educational qualifications of the labour force
- iii) trade-offs between wages and other forms of compensation
- iv) the effects of strikes on wage outcomes
- v) the degree of unionization
- vi) differences between the public and private sectors in terms of employers

In light of the differences observed in this study, the following thoughts are offered regarding wage trends and differences in wages and salaries. First, the gains in elementary teachers salaries can be attributed, in part, to the increase in formal education levels required of teachers in the mid to late 1960s. Increased educational qualifications represent an investment in human capital which, through its contribution to productivity, is reflected in higher wages. Second, college teachers masters in Ontario have done better than average in terms of wage and salary increases and one suspects that increased qualifications have, at least in part, been reflected in higher salaries. This has likely been reinforced by increased bargaining strength over the past twenty years. Third, the relative gains in the health sector are likely a combination of (a)

rapid unionization in the health area and (b) increased education qualifications to support greater and more sophisticated levels of technology.

To test for the validity of one or all of these as factors contributing to relative wage or salary gains, it is necessary to use an econometric model of the following form:

$$X_i = a + bY_i + e_i$$

where X_i represents a measure of real earnings or total compensation of group i , Y the vector of characteristics associated with the i th group and e_i , a random error term. To highlight public and private sector differences for similar occupations, for example, a lawyer in government versus private practice, the expression $g.D_i$ is added where D is the dichotomous variable (set equal to unity if the group is in the public sector, zero otherwise). Alternatively, one can start with the view that the levels are, and will be, different but look for a widening or narrowing of the differences.

It is important to emphasize that this paper only speculates on the relative wage or salary differences for various occupational groups in Ontario. To provide even probabilistic answers, it would be necessary to carefully develop rigorous, testable economic models. While not impossible, such a task is well beyond the scope of this study.
